PYTRAJECTORY USER'S GUIDE

1.1 About PyTrajectory

PyTrajectory is a Python library for the determination of the feed forward control to achieve a transition between desired states of a nonlinear control system.

It's based on a study work written at the Technical University Dresden.

1.2 Usage

1.3 Examples

1.3.1 Translation of the inverse pendulum

An example often used in literature is the inverse pendulum. Here a force F acts on a cart with mass M_w . In addition the cart is connected by a massless rod with a pendulum mass m_p . The mass of the pendulum is concentrated in P_2 and that of the cart in P_1 . The state vector of the system can be specified using the cart's position $x_w(t)$ and the pendulum deflection $\varphi(t)$ and their derivatives.

With the *Lagrangian Formalism* the model has the following state space representation where $u_1 = F$ and $x =$

$$[x_1, x_2, x_3, x_4] = [x_w, \dot{x}_w, \varphi, \dot{\varphi}]$$

$$\begin{aligned}\dot{x}_1 &= x_2 \\ \dot{x}_2 &= \frac{m_p \sin(x_3)(-lx_4^2 + g \cos x_3)}{M_w l + m_p \sin^2(x_3)} + \frac{\cos(x_3)}{M_w l + m_p l \sin^2(x_3)} u_1 \\ \dot{x}_3 &= x_4 \\ \dot{x}_4 &= \frac{\sin(x_3)(-m_p l x_4^2 \cos(x_3) + g(M_w + m_p))}{M_w l + m_p \sin^2(x_3)} + \frac{\cos(x_3)}{M_w l + m_p l \sin^2(x_3)} u_1\end{aligned}$$

A possibly wanted trajectory is the translation of the cart along the x-axis (i.e. by $0.5m$). In the beginning and end of the process the cart and pendulum should remain at rest and the pendulum should be aligned vertically upwards ($\varphi = 0$). As a further condition u should start and end steadily in the rest position ($u(0) = u(T) = 0$). The operating time here is $T = 1[s]$.

```
# import trajectory class and necessary dependencies
from pytrajjectory.trajectory import Trajectory
from sympy import sin, cos
import numpy as np

# define the function that returns the vectorfield
def f(x,u):
    x1, x2, x3, x4 = x          # system state variables
    u1, = u                     # input variable

    l = 0.5                     # length of the pendulum rod
    g = 9.81                    # gravitational acceleration
    M = 1.0                     # mass of the cart
    m = 0.1                     # mass of the pendulum

    s = sin(x3)
    c = cos(x3)

    ff = np.array([
                                x2,
                                m*s*(-l*x4**2+g*c)/(M+m*s**2)+1/(M+m*s**2)*u1,
                                x4,
                                s*(-m*l*x4**2*c+g*(M+m))/(M*l+m*l*s**2)+c/(M*l+l*m*s**2)*u1
                            ])

    return ff

# boundary values at the start (a = 0.0 [s])
xa = [ 0.0,
        0.0,
        0.0,
        0.0]

# boundary values at the end (b = 1.0 [s])
xb = [ 0.5,
        0.0,
        0.0,
        0.0]

# create trajectory object
T = Trajectory(f, a=0.0, b=1.0, xa=xa, xb=xb)

# run iteration
T.startIteration()

# show results
```

`T.plot()`

PYTRAJECTORY MODULES REFERENCE

PyTrajectory is a Python library for the determination of the feed forward control to achieve a transition between desired states of a nonlinear control system.

2.1 trajectory Module

class pytrajectory.trajectory.**Trajectory** (*ff, a=0.0, b=1.0, xa=None, xb=None, g=None, sx=5, su=5, kx=2, delta=2, maxIt=7, eps=0.01, tol=1e-05, algo='leven', use_chains=True*)

Base class of the PyTrajectory project.

Parameters

- **ff** (*callable*) – Vectorfield (rhs) of the control system
- **a** (*float*) – Left border
- **b** (*float*) – Right border
- **xa** (*list*) – Boundary values at the left border
- **xb** (*list*) – Boundary values at the right border
- **g** (*list*) – Boundary values of the input variables
- **sx** (*int*) – Initial number of spline parts for the system variables
- **su** (*int*) – Initial number of spline parts for the input variables
- **kx** (*int*) – Factor for raising the number of spline parts for the system variables
- **delta** (*int*) – Constant for calculation of collocation points
- **maxIt** (*int*) – Maximum number of iterations
- **eps** (*float*) – Tolerance for the solution of the initial value problem
- **tol** (*float*) – Tolerance for the solver of the equation system
- **algo** (*str*) – Solver to use
- **use_chains** (*bool*) – Whether or not to use integrator chains

DG (*c*)

This is the callable function that returns the jacobian matrix of the collocation system.

G (*c*)

This is the callable function that represents the collocation system.

analyseSystem()

Analyses the systems structure and sets values for some of the method parameters.

buildEQS()

Builds the collocation equation system.

checkAccuracy()

Checks whether desired accuracy for the boundary values was reached.

dx(t)

This function returns the left hand sites state at a given (time-) point t .

getGuess()

This method is used to determine a starting value (guess) for the solver of the collocation equation system
→ docu p. 24

initSplines()

This method is used to initialise the temporary splines

iterate()

This method is used to run one iteration

plot()

Just calls `plot()` function from `tools`

setCoeff()

This method is used to create the actual splines by using the numerical solutions to set up the coefficients of the polynomial spline parts of every created spline.

simulate()

This method is used to solve the initial value problem.

solve()

This method is used to solve the collocation equation system.

startIteration()

This is the main loop → [5.1]

u(t)

This function returns the inputs state at a given (time-) point t .

x(t)

This function returns the system state at a given (time-) point t .

2.2 spline Module

```
class pytrajectory.spline.CubicSpline(a=0.0, b=1.0, n=10, tag='', bc=None, bcd=None,
                                      bcdd=None, steady=True)
```

This class provides an object that represents a cubic spline ...

Parameters

- **a** (*float*) – Left border of spline interval.
- **b** (*float*) – Right border of spline interval.
- **n** (*int*) – Number of polynomial parts the spline will be divided into.
- **tag** (*str*) – The ‘name’ of the spline object.
- **bc** (*tuple*) – Boundary values for the spline function itself.

- **bcd** (*tuple*) – Boundary values for the splines 1st derivative
- **b added** (*tuple*) – Boundary values for the splines 2nd derivative
- **steady** (*bool*) – Whether or not to call `makesteady()` when instantiated.

dddf (*x*)

This is just a wrapper for `evalf()` to evaluate the splines 3rd derivative.

ddf (*x*)

This is just a wrapper for `evalf()` to evaluate the splines 2nd derivative.

df (*x*)

This is just a wrapper for `evalf()` to evaluate the splines 1st derivative.

evalf (*x, d*)

bla bla bla

Parameters

- **x** (*float*) – The point to evaluate the spline at
- **d** (*int*) – The derivation order

f (*x*)

This is just a wrapper for `evalf()` to evaluate the spline itself.

makesteady ()

This method sets up and solves equations that satisfy boundary conditions and ensure steadiness and smoothness conditions of the spline in every joining point.

set_coeffs (*c_sol*)

This function is used to set up numerical values for the spline coefficients.

Parameters **c_sol** (*dict*) – Dictionary with coefficient and numerical value

tmp_dddf (*x*)

This is just a wrapper for `tmp_evalf()` with the splines 3rd derivative.

tmp_ddf (*x*)

This is just a wrapper for `tmp_evalf()` with the splines 2nd derivative.

tmp_df (*x*)

This is just a wrapper for `tmp_evalf()` with the splines 1st derivative.

tmp_evalf (*x, d*)

This function returns a matrix and vector to evaluate the spline or a derivative at *x* by multiplying the matrix with numerical values of the independent variables and adding the vector.

Parameters

- **x** (*real*) – The point to evaluate the spline at
- **d** (*int*) – The derivation order

Returns Matrix and vector that represent how the splines coefficients depend on the free parameters.

Return type tuple

tmp_f (*x*)

This is just a wrapper for `tmp_evalf()` with the spline itself.

`pytrajectory.spline.fdiff` (*func*)

This function is used to get the derivative of of a callable splinefunction.

2.3 solver Module

`class pytrajectory.solver.Solver (F, DF, x0, tol=0.01, maxx=10, algo='leven')`

This class provides solver for the collocation equation system.

Parameters

- **F** (*callable*) – The callable function that represents the equation system
- **DF** (*callable*) – The function for the jacobian matrix of the eqs
- **x0** (*numpy.ndarray*) – The start value for the sover
- **tol** (*float*) – The (absolute) tolerance of the solver
- **maxx** (*int*) – The maximum number of iterations of the solver
- **algo** (*str*) – The solver to use

`gauss ()`

`leven ()`

This method is an implementation of the Levenberg-Marquardt-Method to approximatively solve a system of non-linear equations by minimizing

$$\|F'(x_k)(x_{k+1} - x_k) + F(x_k)\|_2^2 + \mu^2 \|x_{k+1} - x_k\|^2$$

`newton ()`

`solve ()`

This is just a wrapper to call the chosen algorithm for solving the equation system

2.4 simulation Module

`class pytrajectory.simulation.Simulation (ff, T, start, u, dt=0.01)`

This class does something ...

Parameters

- **ff** (*callable*) – Vectorfield of the control system
- **T** (*float*) – Simulation time
- **u** (*callable*) – Function of the input variables
- **dt** (*float*) – Time step

`calcStep ()`

`rhs (t, x)`

`simulate ()`

2.5 utilities Module

`class pytrajectory.utilities.BetweenDict (d={})`

Bases: dict

class pytrajectory.utilities.**Grid**

class pytrajectory.utilities.**IntegChain** (*lst*)

This class provides a representation of an integrator chain consisting of sympy symbols ...

Parameters *lst* (*lst*) – Ordered list of elements for the integrator chain

predecessor (*elem*)

This method returns the predecessor of the given element of the integrator chains, i.e. it returns $\int [elem]$

Parameters *elem* (*sympy.Symbol*) – An element of the integrator chain

successor (*elem*)

This method returns the successor of the given element of the integrator chains, i.e. it returns $\frac{d}{dt}[elem]$

Parameters *elem* (*sympy.Symbol*) – An element of the integrator chain

class pytrajectory.utilities.**Model1**

draw (*x, phi, frame, image=0*)

pytrajectory.utilities.**blockdiag** (*M, bshape=None, sparse=False*)

Takes block of shape *bshape* from matrix *M* and creates block diagonal matrix out of them.

Parameters

- **M** (*numpy.ndarray*) – Matrix to take blocks from
- **bshape** (*tuple*) – Shape of one block
- **sparse** (*bool*) – Whether or not to return created matrix as sparse matrix

Examples

```
>>> A = np.ones((4, 2))
>>> print A
[[ 1.  1.]
 [ 1.  1.]
 [ 1.  1.]
 [ 1.  1.]]
>>> B = blockdiag(A, (2, 2))
>>> print B
[[ 1.  1.  0.  0.]
 [ 1.  1.  0.  0.]
 [ 0.  0.  1.  1.]
 [ 0.  0.  1.  1.]
```

pytrajectory.utilities.**plot** (*sim, H, fname=None*)

This method provides graphics for each system variable, manipulated variable and error function and plots the solution of the simulation.

Parameters

- **sim** (*tuple*) – Contains collocation points, and simulation results of system and input variables
- **H** (*dict*) – Dictionary of the callable error functions
- **fname** (*str (optional)*) – If not None, plot will be saved as <fname>.png

class pytrajectory.utilities.**struct**

2.6 log Module

```
pytrajectory.log.IPS(loc=None)
class pytrajectory.log.Logger(fname, mode, suppress)

    write(text)
class pytrajectory.log.Timer(label='~', verbose=True)
pytrajectory.log.err(text, lvl=0)
pytrajectory.log.info(text, lvl=0)
pytrajectory.log.logtime(text, lvl=0)
pytrajectory.log.msg(label, text, lvl=0)
pytrajectory.log.set_file(fname='/usr/bin/sphinx-build2_140407-200320.log', suppress=False)
pytrajectory.log.warn(text, lvl=0)
```
